THE NOTIFIABLE DISEASES

PREVALENCE DURING 1929 IN CITIES OF 10,000 TO 100,000 POPULATION¹

The tables shown on the following pages were compiled from data furnished by the health officers of the cities:

The following is a list of the diseases included:

Anthrax.	Rabies in animals.
Chicken pox.	Rabies in man.
Dengue.	Rocky Mountain spotted fever.
Diphtheria.	Scarlet fever.
Influenza.	Septic sore throat.
Lethargic encephalitis.	Smallpox.
Malaria.	Tuberculosis (all forms and respiratory system).
Measles.	Tularaemia.
Meningococcus meningitis.	Typhoid fever.
Mumps.	Typhus fever.
Pellagra.	Undulant fever.
Pneumonia (all forms).	Whooping cough.
Poliomyelitis (infantile paralysis).	

The present article contains reports from cities having between 10,000 and 100,000 population. It is believed that practically all of these cities are included which have records of morbidity from communicable diseases which are of value for statistical purposes.

No populations are given, as, when the manuscript was prepared, the Bureau of the Census had not estimated populations for 1929, due to the approaching decennial census. When populations are available, rates for the above-named principal communicable diseases will be published in a later publication.

The estimated expectancy, given in the tables for some of the diseases, is the result of an attempt to ascertain from the experience of recent years how many cases of the disease under consideration might be expected in 1929. In most instances the estimated expectancy is the median number of cases reported by the city for the years 1922 to 1928, inclusive. When several epidemics have occurred during these years, or when for other reasons the median is not satisfactory, epidemic years are excluded, and the estimated expectancy is the mean of the number of cases reported for the nonepidemic years. The aim has been to ascertain how many cases of each disease may reasonably be expected in the absence of epidemics.

¹ Data for cities having more than 100,000 population are published in Supplement No. 85.

The column headed "Number of years" shows the number of years since 1921 for which data are available for each city.

In comparing the figures for 1929 with the estimated expectancy, averages, or with reports for preceding years, it should be borne in mind that there has been a gradual improvement in the reporting of communicable diseases during the last few years. An increase in the number of cases reported may be due to better reporting of the particular disease rather than to an increase in the number of cases occurring.

In studying these tables it should be kept in mind that a relatively large number of reported cases of a communicable disease as indicated by a high case rate (and more especially when accompanied by a relatively small number of deaths, as indicated by a low fatality rate) usually means that the health department of the city reporting is active and that the cases of the disease are being well reported by the practicing physicians. It does not usually mean that the disease is more prevalent in that city than in other cities. A high fatality rate may mean that the disease was unusually virulent in a city, that the physicians did not treat the disease in that city with the success usual elsewhere or that the practicing physicians did not report all of their cases to the health department. On the other hand, an unusually low fatality rate may be due to the fact that the disease in the city was unusually mild, that the physicians treated it with unusual success, that the practicing physicians reported their cases satisfactorily, or that the registration of deaths was incomplete or the assignment of the causes of death inaccurate.

Cities which did not report either cases or deaths of a certain disease in 1929 are not included in the table for that disease.

Reported Prevalence for the Year 1929
